1 Gasses and Equation of State

Mole-based Equation	Mass-based Equation
Ideal Gas Constant (R) $pV = nRT$ ($n = \text{mol}$)	Specific Gas Constant (R_s) $pV = mR_sT$ ($m = \text{mass}$)

Table 1: Comparison of Mole-based and Mass-based Ideal Gas Equations

Symbol	Unit	Note
p	Pa	Pressure
V	m ³	Volume
m	kg	Mass
R_s	J·kg ⁻¹ ·K ⁻¹	Specific Gas Constant
R	J·mol ⁻¹ ·K ⁻¹	Ideal Gas Constant
T	K	Temperature
M	kg·mol ⁻¹	Molecular Weight (Molar mass)
n_V	m ⁻³	Number of molecules per unit volume
ρ	kg·m ⁻³	Density
α	m ³ ·kg ⁻¹	Specific Volume
n	–	Moles
N	kg·m·s ⁻²	Newton (force)
Pa	kg·m ⁻¹ ·s ⁻²	Pascal (pressure)
J	kg·m ² ·s ⁻²	Joule (energy)
N_A	mol ⁻¹	Avogadro's Number (6.022×10^{23} particles/mol)

Table 2: Physical symbols, units, and associated meanings

2 Wave Symbols and Quantities

Symbol	Name	Meaning (Wave Context)
λ	Lambda	Wavelength – distance between wave crests (m)
ν	Nu	Frequency – cycles per second ($\text{Hz} = 1/\text{s}$)
$\bar{\nu}$	Nu-bar	Wave number – cycles per meter ($1/\text{m}$)
k	k	Angular (circular) wave number – $k = 2\pi/\lambda$ (rad/m)
ω	Omega	Angular (circular) frequency – $\omega = 2\pi\nu$ (rad/s)
T	T	Period – time per cycle (s)
v_p	v-sub-p	Phase speed – speed at which wave phase propagates (m/s)

Table 3: Wave Symbols and Their Meanings

	λ	ν	$\bar{\nu}$	k	ω
λ	1	$\frac{c}{\nu}$	$\frac{1}{\bar{\nu}}$	$\frac{2\pi}{k}$	$\frac{2\pi c}{\omega}$
ν	$\frac{c}{\lambda}$	1	$c\bar{\nu}$	$\frac{2\pi k}{c}$	$2\pi\omega$
$\bar{\nu}$	$\frac{1}{\lambda}$	$\frac{\nu}{c}$	1	$\frac{2\pi}{k}$	$\frac{2\pi\omega}{c}$
k	$\frac{2\pi}{\lambda}$	$\frac{\nu c}{2\pi}$	$\frac{\bar{\nu}}{2\pi}$	1	$\frac{1}{c\omega}$
ω	$\frac{2\pi c}{\lambda}$	$\frac{\nu}{2\pi}$	$\frac{2\pi\bar{\nu}}{c}$	ck	1

Table 4: Conversion between wave parameters

3 Radiometric Quantities

Quantity	Symbol	Units	Physical Meaning	Equation
Radiant Power (Radiative Flux)	Φ, F	W	Total radiant energy emitted, transferred, or received per second.	$\Phi = \frac{dQ}{dt}$
Radiant Energy (Thermal energy)	Q_e, E, W	J	Total electromagnetic energy accumulated over time.	$Q = \int \Phi(t) dt$
Radiant Power per Unit Area (Irradiance, Radiative Flux Density, Exitance)	E, I	W m^{-2}	Power received per unit surface area (in, through, or out).	$E = \frac{d\Phi}{dA}$
Radiance (Specific Intensity)	L	$\text{W m}^{-2} \text{sr}^{-1}$	Radiant power per unit area per solid angle in a specific direction.	$L = \frac{d^2\Phi}{dA \cos \theta d\omega}$

Table 5: Radiometric Quantities: Symbols, Units, and Definitions

Equation	Name of Equation	Units of Result
$L_{\star} = 4\pi R_{\star}^2 \sigma T_{\star}^4$	Stefan–Boltzmann Law (Star Luminosity)	W (watts)
$F = \frac{L_{\star}}{4\pi d^2}$	Solar Constant / Stellar Flux at Planet	W/m ²
$T_p = \left(\frac{(1-A)F}{\sigma} \right)^{1/4}$	Effective Temperature of a Planet	K (kelvin)

Table 6: Key equations for planetary energy balance

4 Energy Balance

Equation	Name of Equation	Units of Result
$L_{\star} = 4\pi R_{\star}^2 \sigma T_{\star}^4$	Stefan–Boltzmann Law (Star Luminosity)	W (watts)
$F = \frac{L_{\star}}{4\pi d^2}$	Solar Constant / Stellar Flux at Planet	W/m ²
$T_p = \left(\frac{(1-A)F}{\sigma} \right)^{1/4}$	Effective Temperature of a Planet	K (kelvin)

Table 7: Key equations for planetary energy balance

Definition of Values in above Equations:

- $\sigma = 5.67 \times 10^{-8} \text{ W} \cdot \text{m}^{-2} \cdot \text{K}^{-4}$ — Stefan–Boltzmann constant
- R_{\star} = Radius of the star
- d = Distance from star to planet
- T_{\star} = Effective temperature of the star
- T_p = Effective temperature of the planet
- L_{\star} = Stellar luminosity
- F = Flux at the planet
- A = Albedo of the planet

Useful Reference Values:

- $R_{\odot} = 6.96 \times 10^8 \text{ m}$ — Solar radius
- AU = $1.496 \times 10^{11} \text{ m}$ — Astronomical unit

5 Lee

5.1 Beers Law

Gives the change of intensity of light as it passes through a medium;

$$dI_{\lambda} = I_{\lambda}(s + ds) - I_{\lambda}(s) = -I_{\lambda}(s)\beta_e(s) ds$$

can be written as

$$\frac{dI_{\lambda}}{I_{\lambda}} = d \log I_{\lambda} = -\beta_s ds$$

or integrating out

$$I_{\lambda}(s_2) = I_{\lambda}(s_1) \exp \left[- \int_{s_1}^{s_2} \beta_e(s) ds \right] \tag{1}$$

Optical Depth is defined as:

$$\tau(s_1, s_2) = \int_{s_1}^{s_2} \beta_e(s) \, ds \quad (2)$$

5.2 Scattering

For scattering the dimensionless parameter is defined as:

$$x = \frac{2\pi r}{\lambda} \quad (3)$$

which relates the size of the particle with the wavelength. For $x \in (0.2, 0.002)$, we observe Rayleigh scattering. For $x \in (2000, 0.02)$, we observe Mie scattering.

Rayleigh scattering is driven by the electric dipole moment of the photon induces oscillation of the electrons in the atmospheric gases.

Mie scattering is driven by larger particles which scatter on a homogeneous sphere.

They got different patterns for forward and backward scattering.

5.3 Energy Balance

The Earth is in Energy Balance over centuries. Plot of what happens in the atmosphere. Optical transparent, black body at $300K$.

The four main drivers of energy balance are:

- Radiation
- Latent Heat (Tropics)
- Sensible Heat
- Winds

Global Circulation driven by different energy per area in the tropics.

Three transport cells:

- Hadley Cell
- Ferrel Cell
- Polar Cell

What would happen if the Earth was rotating faster?

Coriolis Force is driving the number of transport cells.

Links with the oceans:

Hayline driven with gradient in salinity

6 Review sessions

6.1 Ideal Gas

What is an ideal gas?

Theoretical gas, where particle are moving randomly. The equation of state is given by:

$$pV = RnT \quad (4)$$

where p is the pressure, V the volume, R the gas constant, n the number of particles in mol and T the temperature.

6.2 Mixing ratio vs fraction

The conversion from mixing ratio w to mass fraction X is given by

$$X = \frac{w}{1 + w} \quad (5)$$

To calculate the volume fraction conversion, that depends on the molecular weith of the compounds, we get

$$X_V = \frac{wM_1}{wM_1 + M_2} \quad (6)$$

where M_i is the molecular weith of the gas compounds.

6.3 Adiatat

An *adiabatic* process is a physical process where no heat is exchanged between the system and its surroundings.

For an ideal gas the adiabatic temperature change is given by

$$T_2 = T_1 \left(\frac{p_1}{p_2} \right)^{\frac{1-\gamma}{\gamma}} \quad (7)$$

The potential temperature is the temoerature that an air parcel qwould habve if it were brought to a normal pressuree by adiabatic change. Is is given by

$$\theta(p, T) = T \left(\frac{p}{p_0} \right)^{\frac{1-\gamma}{\gamma}} \approx T \left(\frac{1013}{p} \right)^{0.286} \quad (8)$$

Frequency ν and wavelenth λ are linked by:

$$c = \lambda \nu \quad (9)$$

Radiance measures the electromagnetic radiation emitted from the surface. It quantifies the amount of light flowing in a specific direction. It is given in $\frac{W}{m^2 sr}$. **Spectral radiance** measures the electric radiation emitted from a surface at a specific wavelength. It is given in $\frac{W}{m^2 nmsr}$.

Irradiance measures the total electromagnetic radiation incident on a surface. It is given in units $\frac{W}{m^2}$. **Spectrtal irradiance** measures the irradiance at a specific wavelength, in units of $\frac{W}{m^2 nm}$.

Transmission is given by a number between 0 and 1 that tells us how much of the light thats get into a volume gets out.

The **Optical Thickness** τ measures how mich light is attenuated when passing a medium. It is a dimensionless quantity. Mathematically, it can be represented as

$$\tau = \int_0^L \sigma(z) dz \quad (10)$$

where σ is the extinction coeffitient and L the path length.

6.4 Emissivities

Spectral Emissivity is specific to a specific wavelenght given by

$$\varepsilon_\lambda = \frac{L_{\lambda, object}}{L_{\lambda, blackbody}} \quad (11)$$

Total Hemispherical Emissivity is the integrated emissivity across all wavelengths.

6.5 Solar constants

The solar constants give the total solar irradiance at the top of the atmosphere. For earth, the solar constant is $1361 \frac{W}{m^2}$ and from geometry, the change of the solar constant with the distance is given by $S_0 \propto \frac{1}{r^2}$.

6.6 Planck Law, conversion and devirations

The Planck law describes the spectral distribution of electromagnetic radiation emitted by a black body in thermal equilibrium at a given temperature T . It is given by

$$B_\nu(T) = \frac{2h\nu^3}{c^2} \frac{1}{e^{(h\nu/k_B T)} - 1} \quad (12a)$$

$$B_\lambda(T) = \frac{2hc^2}{\lambda^5} \frac{1}{e^{(hc/\lambda k_B T)} - 1} \quad (12b)$$

For the conversion use

$$\frac{B_\nu}{d\nu} = \frac{B_\lambda}{d\lambda} \quad (13)$$

One can derive the Rayleigh-Jeans law from the Planck law. It is valid for low frequencies / high wavelengths by:

$$\frac{hc}{\lambda k_B T} \ll 1 \quad (14)$$

We then taylor expand the exponential term:

$$\frac{1}{\exp\left(\frac{hc}{\lambda k_B T}\right) - 1} \approx \frac{1}{\frac{hc}{\lambda k_B T}} \quad (15)$$

and be put into Planck's law:

$$B_\lambda(T) = \frac{2ck_B T}{\lambda^4} \quad (16)$$

Conversion to RJ in terms of frequencies as above.

From Planck's law, we can derive Stefan-Boltzmann law by integrating over all wavelengths:

$$M = \sigma T^4 = \int_0^\infty B_\lambda(T) d\lambda \quad (17)$$

One can also derive Wien's displacement law from Planck's law by taking the derivative of B_λ with respect to λ and setting it to zero:

$$\frac{dB_\lambda}{d\lambda} = 0 \quad (18)$$

and leads to

$$\lambda_{\max} = \frac{b}{T} \quad (19)$$

with $b = 2.898 \times 10^{-3} \frac{m \cdot K}{W}$.

Kirchhoff's Law is also important for radiation processes; it relates emissivity and absorption within thermal equilibrium. Key assumptions are thermal equilibrium and steady-state conditions. Mathematically, Kirchhoff's Law states that the emissivity of a surface is equal to its absorptivity. This can be expressed as:

$$\epsilon(\lambda, T) = \alpha(\lambda, T) \quad (20)$$

6.7 Temperatures

Brightness Temperature is the temperature of a blackbody emitting equivalent radiation, it is derived from observed radiation intensity, calculated using Planck's Law inverse.

Effective Temperature is the theoretical temperature of a blackbody radiating same total energy, calculated from total radiant flux from Stefan-Boltzmann law.

$$T_{\text{eff}} = \left(\frac{L}{\sigma} \right)^{\frac{1}{4}} \quad (21)$$

The planetary albedo, a number between 0 and 1 gives us how much light is emitted from a planet.

The greenhouse equation is derived from the energy balance equation, which states that the energy received from the Sun minus the energy emitted by the planet must equal the energy absorbed by the atmosphere. This can be expressed as:

Zero net radiation leaving the top of the atmosphere

$$-\frac{1}{4}S_0(1 - \alpha_p) + \epsilon\sigma T_a^4 + (1 - \epsilon)\sigma T_s^4 = 0 \quad (22a)$$

Zero net radiation entering the atmosphere

$$\frac{1}{4}S_0(1 - \alpha_p) + \epsilon\sigma T_a^4 - \alpha_s^4 = 0 \quad (22b)$$
